Concepts

- Given events A and B:
 - P(A) means finding the probability of A
 - P(A|B) means finding the conditional probability of A (given that B occurs)
 - $P(A \cap B)$ means finding the probability that both A and B occur
 - $P(A \cup B)$ means finding the probability that A occurs or B occurs (this doesn't exclude the situation where both A and B occur)
- For any events A and B, it's true that:

$$P(A|B) = 1 - P(A^{C}|B)$$

 $P(A^{C}|B) = 1 - P(A|B)$

- The order of conditioning is important, so P(A|B) is different P(B|A).
- If event A occurs and the probability of B remains unchanged (and vice versa), then events A and B are said to be **statistically independent** (although the term "independent" is used more often). Mathematically, statistical independence between A and B implies that:

$$P(A) = P(A|B)$$

$$P(B) = P(B|A)$$

$$P(A \cap B) = P(A) \cdot P(B)$$

• If events events A and B are **statistically dependent**, it means that the occurrence of event A changes the probability of event B and vice versa. In mathematical terms, this means that:

$$\begin{split} P\left(A\right) \neq & \ P\left(A|B\right) \\ P\left(B\right) \neq & \ P\left(B|A\right) \\ P\left(A \cap B\right) \neq & \ P\left(A\right) \cdot P\left(B\right) \end{split}$$

• If three events A, B, C are **mutually independent**, then two conditions must hold: they should be pairwise independent, but also independent together. If any of these two conditions doesn't hold, then the events are not mutually independent.

• The multiplication rule for dependent events:

$$P(A \cap B) = P(A) \cdot P(B|A)$$

$$P(A \cap B \cap C) = P(A) \cdot P(B|A) \cdot P(C \mid A \cap B)$$

• The mutliplication rule for independent events:

$$P(A \cap B) = P(A) \cdot P(B)$$

$$P(A \cap B \cap C) = P(A) \cdot P(B) \cdot P(C)$$

$$P(A \cap B \cap ... \cap Y \cap Z) = P(A) \cdot P(B) \cdot ... \cdot P(Y) \cdot P(Z)$$
